It is assumed that future robots must coexist with human beings and behave as their companions. Consequently, the complexities of their tasks would increase. To cope with these complexities, scientists are inclined to adopt the anatomical functions of the brain for the mapping and the navigation in the field of robotics. While admitting the continuous works in improving the brain models and the cognitive mapping for robots’ navigation, we show, in this paper, that learning by imitation leads to a positive effect not only in human behavior but also in the behavior of a multi-robot system. We present the interest of low-level imitation strategy at individual and social levels in the case of robots. Particularly, we show that adding a simple imitation capability to the brain model for building a cognitive map improves the ability of individual cognitive map building and boosts sharing information in an unknown environment. Taking into account the notion of imitative behavior, we also show that the individual discoveries (i.e. goals) could have an effect at the social level and therefore inducing the learning of new behaviors at the individual level. To analyze and validate our hypothesis, a series of experiments has been performed with and without a low-level imitation strategy in the multi-robot system.

Keywords: learning by imitation; imitation; bio-inspired architecture; cognitive map; multi-robot system

1. Introduction

In an unknown environment, interactions among robots can be based on stigmergy [1] which reflects indirect communication through the environmental changes. To share partial knowledge of this environment in a multi-robot system, several benefits can be expected from the imitation capability.[2–6] The imitation strategy can be considered as a powerful tool for autonomous robots based on a bio-inspired architecture to learn and discover new tasks and places. We believe that it is a step forward in bio-inspired architectures (for the navigating robots) by introducing imitation. For instance, RatSLAM algorithm designed by [7] is a bio-inspired simultaneous localization and mapping (SLAM) system based on computational models of rat’s hippocampus or BatSLAM [8] (inspired by Bat’s navigation system), both algorithms provide the way to navigation and mapping, and we come up with the idea on how to accelerate this mapping process by associating hippocampus navigation with imitation strategy.

Modern robotics considers imitation as a powerful behavior that enables learning by observation or imitation [9–15] even if the imitation was not intentional (i.e. imitation emerges from the ambiguity of perception in a simple sensori-motor system).[2] The idea of learning by imitation for robots is inspired by the notion of imitation described by developmental psychologists. According to psychologists, [16] immediate or low-level imitation corresponds to the ability of a child (few months old) to imitate (spontaneously) meaningless gestures. This low-level imitation may serve to higher level functions. It is not only the tool for learning but also a way to communicate and to accelerate the learning process. To highlight the role of the imitation, we started with an experiment (see Figure 1) which describes the success of interaction between a human and a robot.

The goal of this experiment was to allow a robot to follow/imitate the human’s trajectory to discover the positions of the goals in the environment. Indeed, Figure 1 from (a) to (l) shows the discovery of the first and the second goals (G1 and G2) based on the imitation capabilities. The arrows in Figure (e) and (l) show the trajectories of the robot. At this level, the question is to know what would happen if we replace the human by a robot? In this paper, we study the effect of learning by imitation in a multi-robot system which is based on the cognitive map\textsuperscript{1} for navigating and planning. Particularly, we analyze the association of the concept of a very low-level imitation, with our bio-inspired...

architecture which allows the learning and the building of the cognitive map.

This paper is organized as follows: in Section 2, the theory and the bio-inspired architecture of our proposed cognitive map are presented. Section 3 analyzes the impact of the cognitive map’s adaptation in the context of a multi-robot system. Section 4 describes the neuronal architecture for the imitation process. Section 5 details experimental results and
2. A bio-inspired architecture for cognitive map building

Starting from neurobiological hypothesis which highlights the importance of the hippocampus in the spatial navigation, [17] form a model of the cognitive map in the hippocampus representing the entire environment and suggest the shortest paths to a given goal. The model proposed by [18] provides a complete neural architecture of the learning process. The model uses a cognitive map and associates it with a mechanism of action selection.[19,20] Also propose a model of cognitive embedded in a parieto-frontal network, which is based on cortical columns. Based on the same research, different authors [21–24] have disclosed special cells in the rodent’s hippocampus that fire when the animal is at a precise location. These neurons are called place cells (PC). We do not directly use them to navigate, plan, or construct a map, we rather use neurons called transition cells (TC).[25] A transition cell codes a spatio-temporal transition between two PCs that successively win the competition at time $t$ and $t + \delta t$, respectively. The set of the PCs and the TCs constitute a non-Cartesian cognitive map. The reason behind using TC is that their association with an action is univocal and quite straightforward. Thus, there is no need for an external algorithm to extract the action from the cognitive map.

Our architecture takes inspiration from the model presented in [26] which describes the role of the hippocampus. Indeed, the entorhinal cortex which is the main input to the hippocampus (EC) receives signals from associative cortical areas then filters and merges this multi-modal information in order to transfer it to CA3 pyramidal cells and the dentate gyrus (DG). The DG puts the signals together in a temporal hierarchy which later on is re-transmitted to CA3 cells. This temporal hierarchy allows CA3 to be aware of past events and put them in correspondence with present events, therefore the temporal hierarchy behaves like an associative memory through stocking possible transitions between these events. The recognition of the ongoing sequence happens at the level of CA1 using EC and CA3 information. It also extends to the prefrontal cortex (PFC) to serve higher levels of cognitive processes.

To create the PC, the robot takes a visual panorama of the surrounding environment. A camera mounted on a pan system allows to perceive the environment or the surroundings. The visual images are processed to extract visual landmarks. These landmarks are learned and a visual code is created by combining the landmarks and their corresponding azimuth. This configuration serves as a code for PCs. The signals provided by the EC are solely spatial and consistent with spatial cells’ activities. In order to select (only) the cell with the strongest response at a specific location, spatial cells’ activities are submitted to a winner-take-all competition. We subsequently speak about the current location by indicating the spatial cell which have the highest level of activity at a given location. The temporal function at the level of the DG is reduced to the mere memorization of the past location. The acquired association at the level of the CA3 pyramidal cells is then the transition from a location to another besides all information concerning the time spent to carry out this transition. Once the association from the past location and the new one is learned, every new entry will re-activate the corresponding memory in the DG. A schematic view of our architecture is shown in Figure 2.

During the discovery of the environment, the cognitive map is gradually created when the robot moves from one place to another. It is possible that multiple PCs (previously learned) are similar to the current location perceived according to the fixed value of threshold of vigilance. To select a single PC having the strongest response to a specific location, the activities of spatial cells are subjected to a competition called winner-take-all. It allows the identification of the current location by the spatial cell having the highest activity at a given location. The winning activated PC indicates the recognition of this place which is already visited. If none of the PC activates, the current location is considered as an unknown location and this location is learned by another PC and it will be activated on revisiting the same location. The equations which govern the learning process in the cognitive map are given below as Equations (1) and (2):

$$\frac{dW_{ij}^{CC}(t)}{dt} = T(t), \left(Y - W_{ij}^{CC} \cdot X_i^C(t) \cdot X_j^C(t)\right) \left(-W_{ij}^{CC} \cdot \lambda_1 \cdot X_j^C(t) - \lambda_2\right)$$

(1)

$$\frac{dW_{ij}^{MC}(t)}{dt} = S(t) \text{ for } ij = \arg_{ij,k,l} \left(X_i^C(t) \cdot X_{k,l}^C(t)\right)$$

(2)

$T(t)$ is a binary signal (0 or 1) activated when a transition occurs (moving from one place to another). This signal controls the learning of recurrent connections on the cortical map $W^{CC}$. $Y$ is a parameter less than 1 which regulates the distribution of motivation activity on the map. $\lambda_1$ and $\lambda_2$ are, respectively, parameters of active and passive forgetting. $S(t)$ is a signal associated with the goal satisfaction. This signal controls the learning of synaptic connections between neurons in $W^{MC}$ motivations’ activity $X^M$ and neurons of the cognitive map of activity $X^C$. After having explored the environment, the robots are in a position of predicting the locations directly reachable in each situation and to perform a gradient ascent according to their cognitive maps and their associated drives.
3. The adaptation capabilities of the cognitive map

In order to show the robustness of this architecture, we tried to study initially the behavior of a cognitive multi-robot system capable of learning several goals in an unknown environment. Figure 3(a) presents the initial unknown environment with its size of $x = 3.82$ m and $y = 4$ m. The environment is composed of two goals (G1 and G2), two obstacles (O1 and O2), and two identical robots (the robots were equipped by the same tools) with an experiment time frame equal to 30 min and a threshold of vigilance equal to 0.65. The threshold of vigilance (which has a value between 0 and 1) is a variable that controls the learning rate of the neuronal network and in our case also controls the density of PC on the cognitive map. In practice, a new place cell is recruited when the winner cell activity is lower than the vigilance threshold. Thus, when the threshold of vigilance values is high, the robot learns more PC.

Figure 3 shows that our cognitive robots are able to avoid the stable and dynamic obstacles, to navigate, learn, and construct their own cognitive map online (at the same time) in a unknown environment. The shape of the cognitive map in Figure 3(b) or (c) proves that map construction is well related to the robot’s own perception: the different robots learn the environment and the position of the two goals in a different manner, and the number of the PCs is not the same (7 for the first robot, and 9 for the second robot with the same threshold of vigilance).

3.1. Robustness to environment changes

In the previous part, the robots were able to construct their own cognitive map which allows them to navigate and to plan their path in finding goals. To analyze the evolution of the cognitive map, we kept the following parameters unchanged: cognitive map for each robot, the threshold of vigilance, and the duration of the experiment like in the previous experience. Now, we change the structure of environment by increasing its size ($x = 3.82$ m and $y = 7$ m) and by changing the positions of the obstacles (see Figure 4(a)).
Figure 4. The adaptive capability of the cognitive map induced by a changing environment where its new size is $x = 3.82\ m$ and $y = 7\ m$ and G1 and G2 are the goals. Figure (a) and (b) presents, respectively, the evolution of the cognitive map for the first and the second robot.

Figure 5. The components of the RR and the cognitive robot.

Figure 4(b) and (c) shows that, taking into account the new modifications in the environment, both robots were able to continue to adapt their own old cognitive maps while learning the new environment through adding new PCs and TCs. Thus, the changes of the environment did not disturb the robots in their continuous learning of the new environment. This validates the robustness of the cognitive map and capacities to associate and dissociates drives with specific TC on the cognitive map.

4. The neuronal architecture for the imitation process

In order to share a partial knowledge of the environment, direct communication between robots could be used. However, it implies the capability to build some abstract representation of the world which is not present in our model. The presented architecture is based on the stigmergy to communicate between robots. Thus, imitation seems like an interesting way to strengthen this architecture. We describe here a very simple architecture for imitation in a navigation perspective. The proposed model is based on dynamical interactions among mobile robots. Let’s start by showing the components of the reactive robot (RR) and the cognitive robot that we used in our experiments (see Figure 5). It’s important to note that to avoid obstacles we used a Braitenberg mechanism. Indeed, our robots are equipped with IR sensors for the detection and avoidance of obstacles. They see obstacles with five binary sensory inputs associated with five sensors (left, front-left, front, right-front, and right). Robots are then able to know if they are about to face obstacles with a rough indication of their directions.

Our aim is providing limited capabilities to a mobile robot to interact dynamically with other robots by following their current direction of movement. Figure 6 shows the architecture of our imitation model. As shown in
Figure 6. The architecture of our imitation model. Figure (c) shows the neuronal architecture to imitate or follow the other robots depending on the estimation of their velocity vectors (optical flow). Figure (a) presents the optical flow function shown by our neuronal simulator Prometh when the two robots move at the front of the imitator robot. The $+v_e$ and the $-v_e$ are the apparent visual speed in pixel/s. The $+v_e$ (move left) and $-v_e$ (move right) activities are shown, respectively, by black blocks and blue blocks. The intensity or strength of blocks reflects the speed of the respective moving object. Figure (b) describes how an imitator robot perceives the movements of the other robots. We added the arrows to show the motion direction of two robots (presented by the right and left arrows) detected by the robot taking the image.

Figure 6(c), perceived motions (by a camera) in the visual field of the robot are estimated by a classical optical flow algorithm.\cite{27} If the perceived motion is in the upward direction, it is considered as a positive activity. On the other hand, downward motion is accumulated as negative activity. Similarly, motion on the left direction leads to negative activity while movements on the right direction are considered as a positive activity. Figure 6(a) and (b) shows the snapshots taken during the experiment illustrating optical flow functioning. There are two moving objects in the optical field of the robot. One moves left to right and that is transformed into negative activity by the optical flow (shown by blue blocks) while the other moves right to left and that is transformed into positive activity (shown by black blocks). To determine the correct motion direction in following an interacting partner, optical flow activities are transferred to a short-term memory block, this block is used to avoid the fast changes in the environment. Then, all the pixels of short-term memory module are projected on the $x$-axis (i.e. all pixels in each column are added). Winner-takes-all (WTA) selects the highest activated column. This selected column indicates the direction of the movement and the robot can point and follow the interactor.

For this experiment, the resolution of the image is $32 \times 24$ (32 columns or location), these 32 possible locations are realized in 60° (−30° to 30°) circular angles which are fed to the motor according to the corresponding columns (column zero refers to −30° while 32th column corresponds to 30°) and 0° when the agent stands in front of a mobile robot. If two or more visual stimuli are presented at the same time then our proposed imitation algorithm dynamically locates and selects the interacting agent whose estimated velocity vectors are the highest.

5. The positive effect of imitation in the behavior of a multi-robot system

In this part, we try to study the feasibility of our experiments in the multi-robot system. Indeed, we try to show, through two experiments, the positive feedback of the imitation which allows the imitator robot to discover both goals. The first experiment is done with a simple RR which only has an imitation capability. The second one is done with a cognitive robot which has an imitation capability along with the ability to create its own cognitive map. It is also important to mention that in these experiments the imitated robot is never aware of being imitated.

5.1. Imitation performed by a reactive imitator robot

To study the influence of imitation on the behavior of the robots, we added two cognitive robots along with one RR which uses just an imitation strategy. Figure 7 shows at t0, the RR tries to follow one of the two cognitive robots (CR1 and CR2) which are in navigation tasks. Indeed, at t1, the RR detects CR1 and imitates it in its current direction of motion consequently achieving the first goal at time t2. At t3, t4, t5, and t6, the imitation strategy allows the RR to find the second goal with the help of CR2. It is important to note that CR1 and CR2 are faster than the RR. For this reason, at t2, we see that CR1 changes its direction and moves while RR still searches for the goals. Moreover,
5.2. Imitation performed by a cognitive robot

After the discovery of the two goals by the RR through the help of the cognitive robot, the RR is not able to return to the goals on his own again while depending on its needs because it didn’t learn their positions in the environment. The proposal is to combine the imitation strategy with the creation of the cognitive map. Thus, the cognitive imitator robot could create its own cognitive map during the imitation. Once it discovers both goals, it stops the imitation strategy and then it can satisfy its needs by using its cognitive map.

For the sake of simplification, we use a minimal setup (see Figure 8). It includes two goals, three obstacles, and two robots: leader robot LR (which has already learned the environment and the positions of both goals G1 and G2) and the imitative cognitive robot IR (which is capable of imitating and following the other cognitive robot LR and of creating its cognitive map online).

Figure 8(a), (b), (d), and (e) shows that the IR tries to construct its own cognitive map by following the cognitive robot LR (when LR navigates towards the goals using its own cognitive map). Figure 8(c) and (f) demonstrates that the IR has succeeded in discovering both goals G2 and G1 during the imitation process or by following the LR. Throughout the experiments, it was notable that the IR also has the capability of learning and of constructing its own cognitive map (online) independently, but if the same task is performed by using imitation tactic it boosts the performance (as a function of time) of discovering goals and creating a cognitive map. After discovering the positions of both goals, the IR will be able to return alone to the both

at t6, when the RR finds the second goal, the CR2 is already far from the RR. The trajectories of robots demonstrated in Figure 7 allow to further explain the individual behavior of each robot in more details. Indeed, the normal lines show the two cognitive robots’ trajectories when using their cognitive map, the bold lines show the trajectories of the imitator RR, and the red dashed lines show when the cognitive robots CR1 and CR2 were imitated by the RR. The video is available at http://perso-etis.ensea.fr/neurocyber/Videos/Cognitive_Multi-Robot_System/Imitation_CRs-RR.
goals using its own cognitive map. This experiment proves the importance of imitation in multi-robot system. To further understand the robots behaviors, Figure 9 demonstrates the trajectories and the individual behavior of robots in more details. The arrows are the initial positions of the two robots in the environment.

The dashed line traces the trajectory of IR whereas trajectory of LR is shown by the continuous line. IR’s trajectory shows that the robot tries to go to the position of LR when IR detects it in its visual field. It is evident that when IR is close to the LR, its trajectory tries to follow the trajectory of LR (the two trajectories are confounded). The trajectories of the robots show that IR is able to find the two goals G1 and G2 by imitating the trajectory of LR. It is noticeable that the robots do not have localization tools. Thus, we used the robots odometries in order to plot their relative locations and their trajectories in the environment. Indeed, each point of the trajectory is plotted after 4s which is presented by one wheels’ tower.

6. Analysis of the effect of learning by imitation

In order to evaluate the effect of learning by imitation in the multi-robot system, we introduced (i) the goal discovery time (time taken by a robot to discover both goals) and (ii) the number of the PCs. These parameters could characterize the performance of our system.
6.1. The effect of imitation on the goal discovery time

In order to compute the discovering time of both goals in the environment, three different experiments have been tested according to the following scenarios: (i) a single RR in the environment without imitation capability, (ii) the same RR without imitation capability along with a robot that already knows the locations of the goals, and finally (iii) a cognitive imitative robot along with a leader robot that already knows the locations of the goals in the environment.

To find the average time for the goal’s discovery in each scenario, we conducted several tests with the change of the robot’s starting position and also the location of goals. The number of tests to take the average value is determined by the Fisher exact test. It is a statistical test that compares the difference between two variances of two sets of tests (having the same number of observations) by taking the ratio between them according to Equation (3):

\[ F = \frac{S_x^2}{S_y^2} \]  

(3)

where \( S_x^2 \) and \( S_y^2 \) are the variances of two sets of tests. \( S_x^2 \) is the numerator and it always has the larger value between two variances. If the ratio \( F \) does not exceed a certain theoretical value (available in the table of Fisher), it can be accepted. On the other hand, if \( F \) is greater than the theoretical value, we reject the hypothesis of equality of two variances, in this case we increase the number of experiments to close the theoretical value of equality of two variances.

For the first scenario, where a RR (without imitation) looks for goals, we conducted two sets of tests (four tests in each set) and computed the Fisher value \( F = 5.387 \), it is less than 19 which is given in the table of Fisher. For the second scenario, where the same RR explores the environment along with a cognitive robot, we conducted two sets of tests (four tests in each set) and computed the Fisher value \( F > 100 \), it is greater than 19 and unacceptable. To reduce the difference in variance, we conducted another set of tests (4 tests in each set) and computed \( F = 15.79 \), it is less than 19 (does not exceed Fisher’s theoretical value). Finally, for the last scenario, where the imitative cognitive robot imitates the leader cognitive robot to find the goals, we applied two sets of tests (4 tests in each set) and calculated the Fisher value \( F = 2.153 \), it is less than the theoretical value (19).

To have a better comparison, we summarize the results of the Fisher tests by the Table 1:

Table 1. Fisher tests in finding the average time of the goals discovery time.

The average time in finding the two goals for each scenario plotted in Figure 10. Thanks to the learning by imitation strategy, the imitative cognitive robot, which is part of the third scenario, takes less time to find both goals (G1 and G2), its accumulative average time is about 5
Figure 11. The influence of the imitation on the creation of the cognitive map of an imitator cognitive robot. (a) Shows the cognitive map of the LR which already learned the environment and the positions of both goals G1 and G2. (b) Shows the cognitive map of IR that is created after applying the imitation strategy. (c) Presents the two cognitive maps in the same plan. The figure proves the positive effects of the imitation strategy which allows the IR to find the two goals and to create its own cognitive map where its shape is more simple than the LR's cognitive map.

Figure 12. Another aspect of the imitation process.

min (2 min for G1 and 3 min for G2). Once the imitator cognitive robot discovers both goals, its own cognitive map allows it to plan to the goals’ locations. Thus, the imitator cognitive robot is able to better optimize its goals’ discovery time (less than 5 min). However, the RR of the first and second scenarios takes much more time (about three times more) to discover goals. Indeed, for the first scenario, the accumulative average time is 22 min (6 min for G1 and 16 min for G2); similarly, the second scenario takes 19 min (6 min for G1 and 13 min for G2).

The results of the first and the second scenario shown in Figure 10 allow us to analyze the influence of the presence of multi-robot in the same environment. The difference between these scenarios is the way of exploring and accessing the goals. Indeed, in the first scenario, the RR discovers the goals without any difficulty of accessibility. However, in the second scenario, it is not easy to discover them because the cognitive robot (which has already learned the goals’ position) acts as a dynamical obstacle. It means that the RR could lose or win its discovery time. Indeed, when both robots are close to the goal, the RR, instead of heading towards this goal, changes its direction to avoid the dynamical obstacle. However, when both robots are far from the goals, the RR can avoid the dynamical obstacle (the cognitive robot) and finds easily the goals which are available.

6.2. The effect of imitation on the cognitive map
The cognitive map is a way to describe the complexities of the environment. By adding a simple imitation strategy,
we allow the IR to share these complexities and to learn the experience of the LR in order to achieve its goals. Since the IR has the capability of creating its cognitive map, when it follows the trajectory of the LR, its cognitive map will be influenced by the LR. Figure 11(a) and (b) shows the cognitive map of the LR and the IR, respectively. In order to see the difference between the two cognitive maps, we put them in the same plan (see Figure 11(c)).

It is noticeable that there is a similarity between the two cognitive maps at the level of the PCs, TCs, and the shape of the cognitive maps. This similarity shows the positive effects and the success of the imitation process which allows the IR to follow the LR and to discover and learn both goals. As a quantitative measurement, we can analyze the number of the PCs and the TCs. Indeed, we noted that the shape of the IR's cognitive map is more simple than the shape of the LR's cognitive map. Thus, the learning by imitation allowed the IR to optimize its number of PCs (from 12 of LR's PCs to 8 PCs) and also to optimize its TCs (from 30 LR's TCs to 19 TCs) with the same ability to reach both goals G1 and G2, in the same environment as the LR. This optimization could better optimize the IR’s planning time and its goals’ discovery time due to the simplicity of its cognitive map.

6.3. Situations that occurs in the imitation experiments
In the experiments with multi-robot, we noted several situations where the performance of the system decreases regardless of robots used (reactive or cognitive). Figure 12(a) shows that besides the static obstacles, the LR can be a dynamic obstacle in the environment, and instead of following it, the IR has to change its direction to avoid it. Another case appears when the IR tries to follow the LR without knowing whether the LR goes to the goals or not. In this case, the IR may follow the LR to find uninteresting places (see Figure 12(b)). Finally, we can also have accessibility problem (see Figure 12(c)). It occurs when the robot is unable to satisfy its needs because the goal is occupied by another robot. To resolve these situations, integration of emotional mechanism seems necessary.[28] Indeed, the facial expression could be another way of communication which also respects the conditions of the stigmergy. For instance, adding an expressive head on the LR could allow the IR to know when to start the imitation and when to expect the access of the goals.

7. Conclusion
In this paper, we started by revealing the adaptive capability of the cognitive map based on the brain mapping strategies that enable a multi-robot system to adapt in an unknown environment in order to solve navigation tasks. We suggested a set of experiments in real robots that shows how each robot system is able to learn, adapt, and create online cognitive map and how this architecture allows the robots to learn various goals in an unknown environment. We also highlighted the importance of the imitation strategy which boosts the capability (as a function of time) of a cognitive multi-robot system to adapt to an unknown environment. It also allows to solve the navigation task among various targets. Finally, we proved that combining the learning capability with a simple imitation strategy leads (in a real multi-robot system) to a positive feedback both at the individual and the social level. Moreover, it optimizes the time to explore the goals, and it allows the imitator robot IR to create a cognitive map (approximately in the same shape as the Leader robot LR). Thus, to keep the rules of the stigmergy, imitation strategy becomes the way for robots to share knowledge without direct communication. Our architecture which is based on learning by imitation could be used in many areas. For instance, in [29] authors used this architecture to learn trajectories of the robot’s arm. Indeed, the model is based on some dynamical equations which provide a motor control when exploring and converging capacities. A visuo-motor map is used to associate positions of the end effector in the visual space with proprioceptive positions of the robotic arm. It enables a fast learning of the visuo-motor associations without needing to embed a priori information. The controller can be used both for accurate control and interaction.

Notes
1. The cognitive map is a graphical representation of the environment which is related to the perception of each robot. It allows the robot to navigate, to plan, and learn the important places in the environment.
2. The robots were already learned the position of the two goals and created their cognitive map.

He received his MS degree in computer science in 2008 from the National School of Engineers of Sfax (ENIS), Sfax university, Tunisia. His research interests include
cognitive science, collective intelligence, learning by imitation, and multi-robot system.

**Philippe Gaussier** was born in 1967 in Marseille, France. He received the MS degree in electronic from Aix-Marseille University in 1989. In 1992, he received a PhD degree in computer science from the University of Paris XI (Orsay) for a work on the modelization and simulation of a visual system inspired by mammals vision. From 1992 to 1994, he conducted research in neural network (NN) applications and in control of autonomous mobile robots at the Swiss Federal Institute of Technology (LAMI). From 1994 to 1998, he was an assistant professor at the ENSEA. He is now professor at the Cergy-Pontoise University in France and leads the neurocybernetic team of the Image and Signal processing Lab (ETIS). Robots are used as tools to study in ‘real life’ conditions the coherence and the dynamics of different cognitive models (ecological and developmental perspective). New models can then be proposed and lead to new neurobiological or psychological experiments. Currently, his works are focused on one hand on the modelization of the cognitive mechanisms involved in visual perception, motivated navigation, action selection, and on the other hand on the study of the dynamical interactions between individuals (imitation capabilities, social interactions, and collective intelligence). More precisely, his research interests include the modelization of the hippocampus and its relations with prefrontal cortex, the basal ganglia, and other cortical structures like parietal, temporal areas. He is also working on an empirical formalism to analyze and compare different cognitive architectures. This formalism is applied to study the dynamics of the interactions between autonomous systems and their development. Current robotic applications include autonomous and online learning for motivated visual navigation (place learning, visual homing, and object discrimination) and imitation games.

**Syed Khursheed Hasnain** received the MS degree in telecommunication in 2003. He is now working as a PhD student in University of Cergy-Pontoise France and a member of neurocybernetics group of ETIS lab. His research interests are human–robot interaction, imitation strategy in robotics, autonomous robots that can interact with humans based on low-level oscillatory and synchronization properties, and study of dynamical neural network.

**Ilhem Kallel** is an associate professor with the Department of Computer Science and multimedia, ISIMS, University of Sfax-Tunisia. She is a member of the Research Groups on Intelligent Machines (REGIM), National School of Engineers of Sfax. She received the masters degree in computer science in 1988 from the University of Tunis-Tunisia. Going back after an industry experience, she received the PhD degree in Computing System Engineering in 2009 from the University of Sfax-Tunisia. She is the chair of the IEEE SMC Tunisia Chapter for 2013; she is the founder of the ‘IEEE Women In Engineering’ Tunisia section since 2009; she obtains the IEEE-Region8 WIE Clementina Sadwuwa award for 2011. She organizes many scientific and social events. She participates in international research cooperation projects, and in the review process of international conferences and journals. Her research interests include collective and hybrid intelligence, intelligent multirobot systems, fuzzy modeling, multiagent systems, and evolving systems.

**Adel M. Alimi** (S’91, M’96, SM’00). He graduated in Electrical Engineering in 1990. He obtained a PhD and then an HDR both in Electrical & Computer Engineering in 1995 and 2000, respectively. He is full Professor in Electrical Engineering at the University of Sfax since 2006. He is founder and director of the REGIM-Lab. on intelligent Machines. He published more than 300 papers in international indexed journals and conferences, and 20 chapters in edited scientific books. His research interests include applications of intelligent methods (neural networks, fuzzy logic, and evolutionary algorithms) to pattern recognition, robotic systems, vision systems, and industrial processes. He focuses his research on intelligent pattern recognition, learning, analysis, and intelligent control of large-scale complex systems. He was the advisor of 24 PhD thesis. He is the holder of 15 Tunisian patents. He managed funds for 16 international scientific projects. He served as associate editor and member of the editorial board of many international scientific journals (e.g., ‘IEEE Trans. Fuzzy Systems,’ ‘Pattern Recognition Letters,’ ‘NeuroComputing,’ ‘Neural Processing Letters,’ ‘International Journal of Image and Graphics,’ ‘Neural Computing and Applications,’ ‘International Journal of Robotics and Automation,’ ‘International Journal of Systems Science,’ etc.). He was guest editor of several special issues of international journals (e.g. Fuzzy Sets & Systems, Soft Computing, Journal of Decision Systems, Integrated Computer-Aided Engineering, Systems Analysis Modeling and Simulations). He organized many International Conferences ISI’12, NGNS’11, ROBOCOMP’11&10, LOGISTIQUA’11, ACIDCA-ICMI’05, and SCS’04ACIDCA’2000. He has been awarded with the IEEE Outstanding Branch Counselor Award for the IEEE ENIS Student Branch in 2011, with the Tunisian Presidency Award for Scientific Research and Technology in 2010, with the IEEE Certicate Appreciation for contributions as chair of the Tunisia Computational Intelligence Society Chapter in 2010 and 2009, with the IEEE Certicate of Appreciation for contributions as chair of the Tunisia Aerospace and Electronic Systems Society Chapter in 2009, with the IEEE Certicate of Appreciation for contributions as chair of the Tunisia Systems, Man, and Cybernetics Society Chapter in 2009, with the IEEE Outstanding Award for the establishment project of the Tunisia Section in 2008, with the International Neural Network Society (INNS) Certicate of Recognition for contribution on Neural Networks in 2008, with the Tunisian National Order of Merit, at the title of the Education and Science Sector in 2006, with the IEEE Certicate of Appreciation and Recognition of contribution towards establishing IEEE Tunisia Section in 2001 and 2000. He is the founder and chair of many IEEE Chapters in Tunisia section. He is IEEE CIS ECTC Education TF Chair (since 2011), IEEE Sfax Subsection Chair (since 2011), IEEE Systems, Man, and Cybernetics Society Tunisia Chapter Chair (since 2011), IEEE Computer Society Tunisia Chapter Chair (since 2010), IEEE ENIS Student Branch Counselor (since 2010), He served also as expert evaluator for the European Agency for Research. since 2009.
